how do we know how far things are

Ethan Snyder

August 19, 2025

how do we know how far things are?

this will be our leading question

enjoy:)

parallax, mostly

this may be what you're picturing:)

Figure: Parallax as seen looking out a moving car's window⁰.

two types of parallax

two types of parallax

moving parallax

stationary parallax

two types of parallax

moving parallax

involves movement

stationary parallax

does not

two types of parallax

moving parallax

- involves movement
- things close to observer appear to move more, things farther appear to move less

stationary parallax

- does not
- the change in an objects appearance from two different locations (at once or at different times)

two types of parallax

moving parallax

- involves movement
- things close to observer appear to move more, things farther appear to move less

stationary parallax

- does not
- the change in an objects appearance from two different locations (at once or at different times)

(these are actually the same, kinda. motion is just being in two places at different times :))

moving parallax

moving parallax car picture again here look

Figure: Parallax as seen looking out a moving car's window again⁰.

 $^{^{0}}$ Image: https://stock.adobe.com/images/view-out-the-car-window-as-the-scenery-blurs-by/193746850 ($^{\circ}$) $^{\circ}$ $^{\circ}$ $^{\circ}$ $^{\circ}$

stationary parallax

like human eyes, for example this is how depth perception works

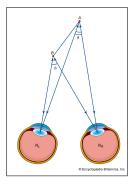

Figure: Eyes doing parallax⁰.

summary

we know how far things are away from us because we have EYES dipshit

ok but what about numbers

like what if we want to MEASURE a distance

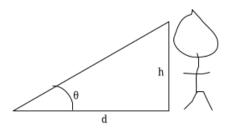

- 1 Introduction
 - Parallax Moving & Stationary
- 2 Measuring Shortish Distances
 - Apparent Size, Units, Measuring Devices
 - Units

 - Galaxies

Apparent Size

What if you know the size of a distant object?

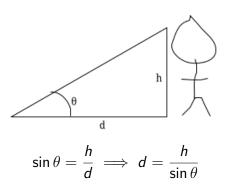

Easiest solution for measuring a distance.

Apparent Size

What if you know the size of a distant object?

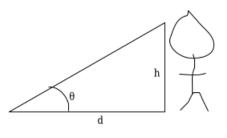

Easiest solution for measuring a distance.

Apparent Size

What if you know the size of a distant object?

Easiest solution for measuring a distance.

$$\sin \theta = \frac{h}{d} \implies d = \frac{h}{\sin \theta}$$

(you just need to know the size of the distant object and be able to measure the angular extent θ)

dawg wt f

what if I don't have a protractor or konw the size of the thing?

Figure: Man scratching his head, confused about how to measure a distance without prior knowledge of a distant object's size or the ability to measure angular extent⁰.

Omage: https://stock.adobe.com/images/portrait-of-a-mixed-race-man-scratching-his-head-in-confusion/68695988

How many things span this distance?

Find something to use as a unit

- Find something to use as a unit
- Find out how many fit span a distance
 - Put many of these objects between and count the number
 - Use the same object and mark intervals of the object, count the intervals

- Find something to use as a unit
- Find out how many fit span a distance
 - Put many of these objects between and count the number
 - Use the same object and mark intervals of the object, count the intervals
- Historically we've used things like a foot but truly make up anything

- Find something to use as a unit
- Find out how many fit span a distance
 - Put many of these objects between and count the number
 - Use the same object and mark intervals of the object, count the intervals
- Historically we've used things like a foot but truly make up anything
- If you want other people to use this unit just make sure their unit is the same as yours

Measuring Devices

Figure: A tape measure and a rolly measurey thing¹.

how far is this fucker?

Figure: Moon².

The Distance Ladder

 $\mathsf{Earth} \implies \mathsf{Moon} \implies \mathsf{Sun} \implies \mathsf{Planets} \implies \mathsf{Stars} \implies \mathsf{Galaxies}$

The Distance Ladder

 $\mathsf{Earth} \implies \mathsf{Moon} \implies \mathsf{Sun} \implies \mathsf{Planets} \implies \mathsf{Stars} \implies \mathsf{Galaxies}$

We need to know each distance/size in order to find out the next object's size/distance.

The Distance Ladder

 $\mathsf{Earth} \implies \mathsf{Moon} \implies \mathsf{Sun} \implies \mathsf{Planets} \implies \mathsf{Stars} \implies \mathsf{Galaxies}$

We need to know each distance/size in order to find out the next object's size/distance.

The goal of measuring the Earth, Moon, Sun, and stars is as old as humanity.

(so let's go back)

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

■ The Moon is closer than the Sun

Solar eclipses, the moon passing between the Earth and Sun

Figure: Partial, total, and annular eclipse images³.

 $[\]mathbf{3}_{\mathsf{Image: https://galamcdougal.blogspot.com/2022/10/solar-eclipse.html}$

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

- The Moon is closer than the Sun (solar eclipses) and same angular size
- The Earth is round

During a lunar eclipse, the Earth passes between a full Moon and the Sun

Figure: Two stages of a lunar eclipse⁴.

4 Images: me :)

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

- The Moon is closer than the Sun (solar eclipses) and same angular size
- The Earth is round (lunar eclipses)
- The Sun, Moon, planets, and stars are cyclical and move in 'perfect circles' around the Earth on a flat plane

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

- The Moon is closer than the Sun (solar eclipses) and same angular size
- The Earth is round (lunar eclipses)
- The Sun, Moon, planets, and stars are cyclical and move in 'perfect circles' around the Earth on a flat plane
 - we were wrong about this but it was a very compelling, mostly unproblematic explanation for a LONG time

What have we always known?

(This is essentially the same question as what can be observed with the eyes.)

- The Moon is closer than the Sun (solar eclipses) and same angular size
- The Earth is round (lunar eclipses)
- The Sun, Moon, planets, and stars are cyclical and move in 'perfect circles' around the Earth on a flat plane
 - we were wrong about this but it was a very compelling, mostly unproblematic explanation for a LONG time
 - we also knew slower moving things were farther (parallax), so we knew Jupiter and Saturn are far and Venus and Mars are close

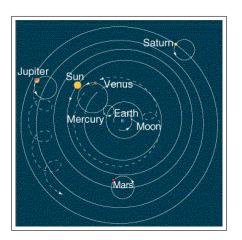

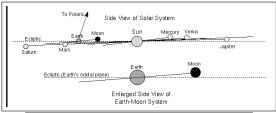

Figure: Geocentric model with subcircles that explain retrograde motion⁵.

4□ ► 4□ ► 4 = ► 4 = ► 9 < 0</p>

 $[\]mathbf{5}_{\mathsf{Image: https://starrythoughts.weebly.com/uploads/1/6/3/0/16304784/2180964_orig.gif}$

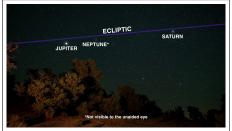

Figure: Ecliptic visuals⁶.

⁶ Images: https://www.astronomynotes.com/nakedeye/phases/solarsys.gif, NASA

In summary,

(this information is all we needed to figure out the distance to the stars. the rest is all measurements and math)

- The Earth is spherical
- The Moon is closer than the Sun and same angular size
- All solar system bodies orbit in a flat plane in perfect circles around the Earth

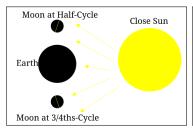

In summary,

(this information is all we needed to figure out the distance to the stars. the rest is all measurements and math)

- The Earth is spherical
- The Moon is closer than the Sun and same angular size
- All solar system bodies orbit in a flat plane in perfect circles around the Earth
 - (no physics behind this, but it was a pretty viable, elegant explanation)

Aristarchus of Samos, Greek, 270BC, Heliocentrist

Realized the distance of the sun would change when we observe a half-moon. Instead of starting humble with the size of the Earth browent wacko and tried to get THIS distance first.

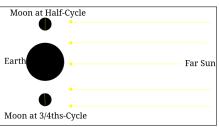

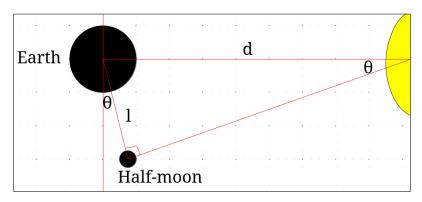

Figure: Near-Sun rays make a half-moon appear sooner in the lunar cycle, while far-Sun parallel rays mean half-moons happen at $\frac{1}{2}$ and $\frac{3}{4}$ in the lunar cycle.

Aristarchus' Method

Measure the angle θ at exactly half-moon.

$$\sin \theta = \frac{l}{d} \implies \frac{l}{d} = \sin \theta$$

Aristarchus of Samos, Greek, 270BC, Heliocentrist

The issue here is incredibly precise timing — when is it exactly half-moon?

Aristarchus of Samos, Greek, 270BC, Heliocentrist

The issue here is incredibly precise timing — when is it exactly half-moon?

The lunar cycle is 29.5 days (which was known)

Nowadays, we know that half-moons occur 30 mins after it reaches those 90° marks

This meant measuring $\frac{1}{1400}$ th of a lunar cycle.

Aristarchus of Samos, Greek, 270BC, Heliocentrist

The issue here is incredibly precise timing — when is it exactly half-moon?

The lunar cycle is 29.5 days (which was known)

Nowadays, we know that half-moons occur 30 mins after it reaches those 90° marks

This meant measuring $\frac{1}{1400}$ th of a lunar cycle.

Aristarchus measured 87°, meaning $\frac{1}{d} = \sin(90^{\circ} - 87^{\circ}) = 19.1$ the Sun is 19x farther away than the Moon.

In reality, this half-moon angle is 89.88°, which gives a much larger number: the Sun is 409x farther away than the Moon.

Aristarchus of Samos, Greek, 270BC, Heliocentrist

good effort dipshit

Greece, 230BC

The first good measurement of the size of the Earth

Greece, 230BC

The first good measurement of the size of the Earth

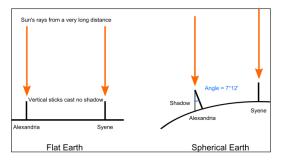

Figure: Eratosthenes' experimental setup⁷.

Image: https://www.mezzacotta.net/100proofs/images/002-SyeneAlexandria.png

Greece, 230BC

Eratosthenes knew the city of Syene was on the Tropic of Cancer (no shadows on summer solstice, sun right overhead)

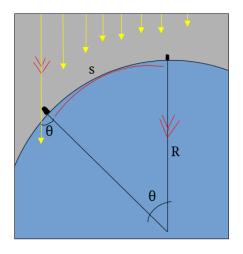

He also knew the distance between Alexandria and Syene

Figure: Alexandria and Syene along the Nile River in Egypt⁸.

esearchgate.net/profile/Alok-Kumar-111/publication/253596660/figure/fig2/

Eratosthenes' Method

Arc length:

$$s = \frac{\pi R t}{180}$$

Rearrange for R, Earth's radius:

$$R = \frac{180s}{\pi \theta}$$

s was already known from geographical data, and θ was measureable from shadows cast in Alexandria.

Greece, 230BC

To avoid doing difficult division with π , he opted to calculate the circumference, not the radius:

$$C=2\pi R=\frac{360s}{\theta}$$

To which he found a value of 252,000 stadia.

In ancient Greece, they used a unit called a 'stade'. We don't really know how big a stade was, but we estimate 1 stade is about 525ft, making his calculation *less than 1% off.*

Eratosthenes: 25,050mi. Modern value: 24,901mi.

Hipparchus and the Distance to the Moon

Greece, 189BC

Looking at a solar eclipse from two different places allowed for the calculation of the distance to the moon.

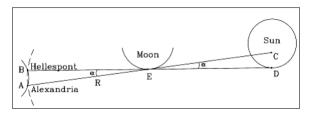

Figure: Parallax configuration that allowed our boy to measure the size of the moon⁹.

Image: https://pwg.gsfc.nasa.gov/stargaze/Shipparc.htm

Hipparchus

Enjoy this drawing, I'm getting lazier and I'm just going to use MSPaint

How far is the sun?

This would've been really complicated math, but the moon and the sun happen to be the same apparent size

Because the moon and the sun are the same apparent size in the sky, and since we know how big and far the moon is. . .

We know that if the sun is x times further than the moon, that is must also be x times larger.

How far are the stars?

We can only calculate this if we know the astronomical unit (AU)

How far are galaxies?

Galaxies are so distant that they have no apparent motion due to parallax. It's too small to measure.

This is where all the really neat fun geometry breaks down and it just gets to grueling modern science of measuring light and doing really hard math.
